Why label?

The case for a common reference frame

- (1) to communicate and compare results
- (2) to classify data
- (3) to discover patterns in data

Why label?

The case for a common reference frame

- (1) to communicate and compare results
 - across subjects
 - across conditions
 - across time
 - across brain imaging techniques

- (2) to classify data
 - Parceling a brain into regions of interest provides a natural way to parcel (cluster) data acquired from a brain.

- to discover patterns in data
 - The spatial arrangement and connectivity of brain regions can reflect an underlying pattern in the distribution of data acquired from those regions.

The above all rely on the use of a common reference frame (labeling system). To establish correspondences across brains, brain image data must be coregistered (spatially normalized).

Evaluation

Label agreement metrics:

V_a	= intersection with the same label	=	
V_c	= comparison volume	=	?

intersection = $V_a /$ intersection of atlas and subject = $= \frac{\sum |A_i \cap M_i|}{\sum |A \cap M_i|}$

overlap = $V_a /$ union of atlas and subject = $= \frac{\sum |A_i \cap M_i|}{\sum |A_i \cup M_i|}$

mask overlap } = $V_a /$ subject = $= \frac{\sum |A_i \cap M_i|}{\sum |M_i|}$

filled mask overlap

Evaluation

A one-way ANOVA was performed to test if the means are the same for the label agreements obtained by each of the methods.

A multiple comparison test was then performed to determine which pair of means are significantly different (95% confidence interval, based on the Studentized range distribution).

Evaluation

An atlas was used to label an artificially lesioned version of itself.

Single atlas

Atlas

- Labels**
- frontal pole
 - superior frontal
 - middle frontal
 - inferior frontal
 - orbital (frontal)
 - precentral
 - postcentral
 - superior parietal
 - inferior parietal
 - temporal pole
 - superior temporal
 - middle temporal
 - inferior temporal
 - fusiform
 - lingual/parahippocampal
 - occipital lobe
 - cingulate
 - insula

Mindboggle future directions

Atlas labels	New boundary definitions reflecting: Functional and physiological data Tractography (diffusion-weighted imaging) Microstructural data Multispectral data
Image processing	New methods for extracting sulcus pieces, labeling
Matching structures	Different distance metrics Statistical attributes of sulci Multiscale and ordered comparisons
Combining labels	Alternatives to majority voting rule (weighted matches) Aggregate matching costs to construct a probabilistic atlas
Evaluating results	Treat regions differently with regard to size, variability, etc.
Software distribution	Join the NiPy project
Some applied research	Pattern matching and prediction Morphogenesis Information visualization
